

A Lifecycle Approach towards Business Rules Management

Matthew L. Nelson, Illinois State University, mlnelso@ilstu.edu

Robert L. Rariden, Illinois State University, rariden@ilstu.edu

Ravi Sen, Texas A&M University, rsen@mays.tamu.edu

Abstract

Automating business rules management has provided significant benefits including greater control, improved flexibility, and the ability to rapidly deploy business rules across processes, information systems and channels (web, legacy, wireless and otherwise). These benefits, in addition to trends in service orientated architectures, web semantics, and business process management, have spawned an emerging business rules engine (BRE) market. Despite these developments, little has been published in MIS journals that examine the management of business rules management systems (BRMS) development and deployments. Making use of structuration research methods, we collect data from leading developers, end-users, researchers and thought-leaders from the industry. Data collection results revealed a business rules management lifecycle inclusive of these steps: align, capture, organize, author, distribute, test, apply, maintain. The contextual influences, actors, inputs, outputs and artifacts are identified in each step. Academic and managerial contributions, as well as recommendations for future research are provided.

1. Introduction

Whether we realize it or not, we're confronted with business rules (BR) numerous times on a daily basis. Take for example, a simple trip to the grocery store. From a *competitive perspective*, business rules are structured around which items are offered at a sales discount, the duration of the discount, and conditions of the discount. From a *regulatory perspective*, business rules require restricted consumer access to some goods, prescribe which items can (and cannot) be shelved with other goods and define the allowable shelf duration of still other goods. From an *industry norm perspective*, business rules are used to outline the types of certain check-out lanes, which goods are placed near exits / entrances, and return policies. From a *legislative perspective*, business rules dictate the appropriate sales tax rate on categories of goods, require proof of attainment of a minimum age prior to the purchase of other goods, and require a prescription from a licensed medical doctor prior to the purchase of

still other goods. It's not difficult to imagine that a single item, such as a prescription strength liquid cough syrup, may be affected by all twelve of the above rules. Grocery stores stock thousands of items, with high turnover rates, impacted by hundreds of different business rules from a variety of sources. These rules are embedded throughout the store's point-of-sale systems, inventory systems, promotion systems, accounts payable, product placement systems and their associated business processes. This was a trip through a grocery store. When one considers the volatility to which business rules are added or changed in businesses that transcend time zones, seasons, information systems, statutory boundaries and channels (web, legacy, wireless or otherwise), the complexity of BR management can grow on an exponential basis.

1.1 Business Rule Management Benefits

Fortunately, there has been research and development to assist organizations with many of the technical challenges associated with business rules. In industry, for example, vendors such as ILOG SA, Blaze AdvisorTM and Pega Systems, Inc. have been developing business rule engines (BRE) since the late 1980s and are now leaders in an emerging BRE segment [7, 26]. In academia, the computer sciences and engineering outlets have been active in BR research, with extensive studies in rule programming, meta-modeling, rule mining, rules engines, business user interfaces and their role in services orientated architectures (SOA). Furthermore, joint academic and industry developed Object Management Group's (OMG) Semantics of Business Vocabulary and Business Rules (SBVR) standards (released in September 2006), which is intended to provide standards surrounding BR structure, terminology, classifications and meaning in BR authoring and repositories [50].

This research and development is beginning to pay-off. The BRE market has grown to a half billion U.S. dollars in annual product sales with more than 50 vendors worldwide [16]. The drivers underlying this growth are the benefits enabled to organizations with effective BREs including improved interoperability,

greater flexibility and control over deploying BRs across channels and systems, enhanced quality of BR updates, reduced cost and greater speed of implementing rule updates. Furthermore, the SBVR release may begin to provide a foundation for extending these benefits beyond the enterprise level and into supply-chains and industrial groups.

1.2 Research Questions

Despite this substantial progress in business rules research, there has been little published in MIS academic outlets relating to the business rules topic and more specifically to managing BR developments and deployments. The research and development presented thus far is traditionally at a micro-level, pertaining to technical considerations such as rule engines, rule mining, rule authoring and interfaces. BR automation, however, is a quintessential example of the integration of business process, information technology and human interaction. Organizations need an understanding of the entire BR perspective and context from development through implementation. For example, the IRS recently spent a considerable amount of money and time in formal solicitation and evaluating bids from BRE vendors, only to realize during an audit of the bidding process by an inspector general that a BRE was not actually required for their business rules project and a should have only been considered under certain conditions [35]. In another widely publicized BR project failure, the Government of Canada's CAN\$300 million initial business rules project failure was due (in part) to front loading the project with a plethora of related (but out of scope) initiatives such as legacy systems modernization efforts [9]. Finally, Australia's Department of Family and Community Services found that 34 versions of a BR vendor's contract existed and had been changed 129 times. The estimated cost of project failure is AU\$64 million [40].

As the business drivers for automating BRs in organizations continue to grow and the benefits of BR automation continue to be realized, the need for viewing BR management at a higher contextual level and with a broader lifecycle perspective are mounting. Indeed, BR project management and implementation failures (such as those described above) are growing more commonplace in the absence of such studies. We seek to raise the level of discussion by considering the entire business rule management lifecycle with greater breadth, than depth and examining the larger context to which BR management fits in an organization. The underlying research questions include, *does a general process or lifecycle exist that organizations follow when automating and managing business rules? What steps are involved and what*

effective practices can be solicited from these organizations to prevent project derailment?

By utilizing a structuration lens, we explore these questions through a literature search, structured interviews and data collection from leading BR end-users, developers, and thought leaders. The study was conducted during two time periods (set 12 months apart) and the results synthesized, using techniques in structuration MIS literature to develop a business rules management lifecycle (BRMLC). The academic contributions include identification of initial BR research streams, highlighting distinctions between knowledge management versus business rules management lifecycles, extending structuration techniques into the BR area and describing the BR fit into the larger service science, management and engineering (SSME) research context with similar initiatives such as SOA, process management, workflows, web semantics and the management of BRMS. Managerial contributions include an understanding of how organizations are managing their BR automation implementations, a broader perspective of the full BRMLC from initiation through maintenance and how BR management fits into the larger enterprise wide context.

2. A Literature Review of Business Rules Management Systems (BRMS)

A literature search was conducted to better understand the extent, type, and streams of BR related research. The formal search focused in MIS academic journals, with less structured searches in computer science and engineering related journals and the business press.

2.1 Literature Review Methodology

The primarily literature review encompassed academic MIS journals covering time periods from the late 1980's through first quarter 2007. This time period was selected to coincide with origins and developments of modern-day BRMS in academia and industry. The journals were selected based on their ranking and propensity to publish articles relating to decision management and rules-based technologies. An all text search (inclusive of abstracts, titles, keywords, text) was utilized with the following phrases "business rule(s)", "rule(s) based", "externalization" and "rule mining". The matches were then reviewed to determine the extent to which the manuscript discussed specific BR topics. The irrelevant matches were dropped and the retained manuscripts were grouped into distinct segments in the business rules

management space. The manuscripts were coded and the results are summarized below.

2.2 Distinguishing BRMS

Modern-day BRMS has its roots in early artificial intelligence (AI), expert systems and more recently in knowledge management systems. Arguably, the mid to late 1980s is when the modern-day BRs segment began to distinguish itself from the AI and expert systems arenas. Researchers and developers began to realize the practical real-world applications of the initial artificial intelligence systems. As Sheil comments in her 1987 *Harvard Business Review* article about the practical short-comings of large-scale AI systems, *“The ability to provide highly customized, integrated applications software has turned out to be a major strength of AI technology. The short term value is clear....rules-based programming are an effective way to arrive at a clear, concise, yet easily extended statement of the logic underlying many discrimination and classification tasks. The simple rules-based interpreter is an effective technology for a wide-class of simple, practical problems.”* [52, pages 91-97].

Sheil continues in the article to advocate the automation of these routine daily decisions and to evaluate the execution of these decisions along five lines: consistency, precision, speed, agility and cost. The author was not alone in this sentiment, since it was during this timeframe that initial development of many of the now dominant modern-day BRE in the market place began in earnest: Gensym Corporation’s G2 in 1986 by a university professor, Haley Systems, Inc. in 1989 by a medical student, ILOG SA in 1985 by a French university professor and Blaze AdvisorTM in 1988 [7, 17, 22, 26].

2.3 Results from MIS Literature Survey

The search resulted in 32 articles from MIS journals over the past 20 years (designated with a superscript 1 in References). The manuscript groupings resulted in six emerging focal areas of business rules related research in the MIS journals, including an examination of business drivers associated with BRMS, rule mining, BR repositories (including rule authoring, modeling, user interfaces), automating BR (including BR engines and web-services), BR in the context of workflow management, and domain specific studies (that examined BR use in a narrowly defined industry or market segment).

Overall, the largest number of articles examine the business drivers pushing organizations towards IS architectural integration [24], IS infrastructure

flexibility [14] and integration [28], the use of BR in B2B e-commerce models [54], the effect of little decisions adding up [47] and dynamic synchronization of strategy and IT [45]. Several domain specific studies have examined rules-based implementations including lower back pain diagnostics [33], assignment of technicians to service faults [31], forecasting S&P 500 index futures [56], build-to-order [27], customer order scheduling [8] and others. MIS researchers have also studied BR automation with the use of a BR engine [13], without the use of an inference engine [25], using goals to design and verify a rule base [10] and detecting anomalies in hybrid knowledge-based systems [36]. There have also been select recent articles that have related the BR context to other organizational initiatives such as mobile devices, business processes [46, 11], and inter-organizational workflows [57]. Finally, one study indirectly discussed the use of a rule repository through the use of managing metadata in data warehouses [51] and two studies examined the potential use of common data mining techniques in BR mining through reverse software engineering [58] and a three-tiered knowledge management discovery [49].

These studies provide beginnings of a BR research program, but collectively the research often overlooks major steps in BR management and fails to focus on BR specific issues and the larger context that rules play in organizations. For example, the architectural integration and flexibility studies discuss the general benefits of these initiatives, but only indirectly present the role that BRs contribute. The same was found in data mining and knowledge management discovery manuscripts. Important dynamics in BR management are also excluded, such as IT ~ business alignment and the separation of the rule management and implementation environments. Important steps in managing BRs are also overlooked such as developing an organization-wide BR meta-model and the need for a stand alone (independent) rules repository. More profoundly, little was found on managing BR related development projects or other ties that BR projects have with related emerging enterprise wide initiatives (active *real-time* decision making, systems integration across channels and applications, enterprise wide agility and others). The few studies found with lifecycle perspectives [38, 1] focus on knowledge management systems and production decision support systems, as opposed to modern-day BRMS. These lifecycles can act as a good starting point, but need more specificity in a BR context.

3.0 Research Methodology

To address the research questions, a structuration

lens is employed in the research design, with an emphasis towards developing a process model explanation. Structuration theory is one of the most widely and effectively used methods by IS researchers [43, 44]. Consistent with many IS studies where preliminary indicators suggest that a *de facto* process used by organizations exists, we take a positivist stance with this study [41]. An interior perspective and a constitutive mode of analysis were intentionally utilized in the study's design to better insure compatible alignment of process steps that transcend organizations and actors [43]. Qualitative research methods are employed with emphasis on structured but open-ended interviews with process actors including industry thought leaders, developers, end-users, and other stakeholders. Although the authors do not necessarily claim this paper qualifies as an ethnographic study, additional qualitative data collection techniques were utilized to better acclimate the authors to the stakeholders in the industry including on-site visits, meeting presentations, reviewing company documents, industry white-papers, case studies and others [37].

Our research methods, interview questions, and process step descriptions are influenced by Klein and Myers' [29] principles in conducting interpretive field research, Poole and Descantis' [43] seven interlocking requirements for structuration research and Pozzebon and Pinsonneault's [44] assessment of structuration theory in the IS field. Based on choices in the structuration research [43], the level of analysis is a *global* level (identifying the BR process that is traditionally followed across organizations), with a *related structures* focus (narrowly focused on a closely related group of structures), with a framing perspective focused from a structure view (at an overall process level) with the focus shifting towards an *actors* view at the individual process step level. The dynamics focus is simply acknowledging higher order process steps exist, with an emphasis on *system stability* (as opposed to *system changes*), all with a *positive* stance.

3.1 Respondent Profiles

57 organizations participated in the structured interviews in the first round of data collection and 51 (90%) were available and agreed to participate in the second round. Interviews were conducted during the 2nd quarter of 2005 and 2006, respectively. See Table 1 for the list of structured questions / topics. Three members of the research team were present during interview sessions. The same principal investigator led participants through the structured questions, while all research team members took notes. The research team

conducted "clean-up" sessions after interviews to compare responses. Interview sessions lasted two and one-half hours (on average).

The participating organizations had three to four representatives in each session. At a minimum, this group would include a BR implementation project manager (with a business focus) and a BR technical representative (e.g. developer, architect, engineer). Thirteen sessions included the organization's CEO / founder and six sessions also included the organization's CTO / CIO. Four sessions included thought leaders from the BR industry including two business rule handbook authors, a research scientist from the Software Engineering Institute at Carnegie Mellon and a member of the SBVR initiative. In total, the individual respondents had direct experience with 513 BRMS implementations. One hundred invitations were extended to the identified pool of potential respondents. Potential respondents were selected based on their organization's involvement in BR product development, services, end-users and other BR industry stakeholders. A review of published case studies, industry white papers and other business press were reviewed to identify firms that have demonstrated a willingness to discuss their BR implementations.

4.0 Findings

Figure #1 contains the BRMLC as synthesized from the research methodology and setting. The eight steps in a nutshell, include *alignment / plan* of the respective BR domains with the organization's overarching data model and strategy; *capture* rules from the various sources; *organize* the rules and begin managing them in rules *authoring*. Once the business rules are centrally stored and managed, then begin *distributing* (or sharing) the rules, *test* the rules for interoperability and *apply* 'go live' with the automation, and finally *maintain*.

Three important characteristics of this structuration should be highlighted at the outset. First, depicting the BRMLC in this manner provides a picture of the entire perspective (regardless of the domain), as opposed to the literature survey results that focused on narrow or omitted segments. Second, lifecycle steps can be grouped into three higher level environments of *align, rule management* and *implementation* (see Figure 2). Third, considering the three environments from a higher contextual perspective allows us to examine how they interact and vary, within the larger context of the organization and the BRMLC. For example, *alignment* is primarily a business strategy activity that's led by senior business

and IT leaders, *rule management* is a business operations activity that is owned by business staff, and the *implementation environment* is primarily the responsibility of IT. The rate of change in *align* is slow, varying with the organization's overall mission and strategic direction. The rate of change in the *rule management* can reach high levels, depending on rule volumes, volatility and others. The *implementation environment* will experience a slower rate of change, depending on the firm's technological infrastructure, IT direction, and platforms. *Alignment* has a longer-term focus, influenced by the firm's direction and vision. *Rule management* will have a short-term focus, a need for a real-time active decision making, and is influenced by SBVR and the industry's web semantic standards. The *implementation environment* has a mid-range focus and influenced by an array of related top-level initiatives such as SOA, workflow, process and channel management. Detailed descriptions of each step are provided below. As recommended in the structuration literature, each step includes highlights of the step's inputs, outputs, processes, actors and effects.

4.1 Align

The first step is to develop an organization wide strategy and plan for deploying BR management projects and aligning the plan with similar enterprise wide initiatives. The actors include senior management from the business and IT staff. Major activities include segmenting the universe of BRs impacting the organization into logical domains (e.g. by lines of business) and an analysis of business drivers underlying those domains. Resources and other artifacts include the organization's overarching data model, their strategic IT vision, including the systems integration plans for the enterprise and beyond. The output includes a high-level BR deployment plan organized by business segments, relations between the segments, priority areas, sequencing, tentative timelines and how the plan fits with similar organization wide initiatives such as SOA, semantics, and IT ~ business alignment. The effects of this step include consistency with similar initiatives, maximizing the opportunity for rule reuse in later stages, and a BR management deployment roadmap driven by business needs. Additional insights from respondents emphasized the need to keep initial BRMS deployments small (and manageable) and a profound regret for sometimes overlooking this step.

4.2 Capture

Identification of potential BRs impacting the domain segment in development. The actors include BR business and IT staff, rule mining vendors, domain

experts (from industry and the firm), longer-term employees and others. The resources and artifacts include user manuals, legacy system code, business contracts, legislation, memos, e-mails, procedure manuals and others. The outputs will provide identification of an exhaustive list of potential BRs influencing the chosen business segment. The procedures include data mining software that sweeps legacy code (a.k.a. rule mining), user manuals, business contracts, legislation and interviews with longer-term employees [34]. The effects of this step include exposing and formally identifying potential BRs that would otherwise be buried. Indirect effects include significant improvements in business process transparency and program code efficiency opportunities. Additional insights from respondents emphasized the need to remain focused on BR management during this step due to the volume of process reengineering, program code remediation and other efficiency opportunities that are exposed. Paulson and Wand's [42] and more recently Torino and Politecnico [55] earlier studies in the legacy code efficiency techniques provide additional insights.

4.3 Organize

After the capture step identifies potential BRs, the extraction process involves verification that the item is a BR and an initial organization of the rules. The actors include the organization's BR business and IT representatives and domain experts. The inputs include the potential BRs identified in the prior step and the output is validated BRs and rule sets, with preliminary plans for *where* and *how* the rules will be implemented and updated. The rule outputs from this step are ready to be formally authored BRs. This step is traditionally time consuming and necessitates extensive manual intervention and analysis. Key procedures include removing out-of-scope or otherwise invalid BRs from capture results, assessing the quality of BR sources, grouping rules in to related rule sets, and preparing rule update procedures (ownership, frequency, timing). Additional procedures also include a mapping of *where* the rule will be implemented (systems, processes, layers) and *how* the installation will occur. The effects of this step include substantial rule authoring time savings through elimination of redundant, out-of-scope, or non-BRs prior to the authoring process. Halle [23] and Ross [48] provide useful additional resources for organizing BRs, and others provide detailed suggestions for conducting BR pattern analysis [19].

4.4 Author

The thrust of step four is the conversion of implicit

data into explicit knowledge through formal BR authoring. Actors in this step include the BR business staff, the firm's management whom have authorization to make the BR decisions, and domain experts who assist with interpreting contractual and legislative business rules [48]. Inputs include the organized BRs from the prior step and outputs include a fully authored business rule in a BR repository. The BR repository is *designed for* and *managed by* the organization's business representatives (as opposed to the IT staff) in a user-friendly environment that makes use of standard business terminology (as opposed to programming code). Optimally, the BR repository should be centrally managed, independent from the implementation environment, owned and operated by the organization's *business* BR representatives. Establishing the repository in this manner is important towards enabling a dynamic shift from IT owning / managing BR updates back to business users. In essence, this permits the business staff to focus on their strengths (rule authoring and management) and permits the IT staff to focus on their strengths (managing the implementation environment). Logic testing is included in authoring procedures as well, such as rule ambiguity, accuracy, completeness, and redundancy tests. Artifacts and resources include hand-books that provide in-depth business rules authoring from a business perspective [23, 48], managing rule sets and aligning BR with the organization's information systems [33] and with service orientated architecture initiatives [19]. The OMG's release of an adopted specification SBVR in 2006 is also an important artifact [50]. Its release through the OMG should provide significant strides in uniformity of rule authoring across organizational boundaries and industrial groups. Effects of this step include an enhanced understanding and communication of rules, higher quality rule development, enables a shift in control of rule updates from IT to the business staff, facilitates a clear distinction between the *rule management* versus the *implementation* environments, and affords the firm greater flexibility in selection of a technical implementation solution.

4.5 Distribute

This step requires sharing (or distributing) formally authored BR from the rule repository to the selected implementation environment(s). Inputs include BR from the rule repository and information from the *organize* step that includes preliminary assessments of where the rule needs to be implemented (systems, processes, layer) and how the installation will occur. Ownership in the BRMLC now shifts to the IT staff to build-out the implementation environment(s). A

seamless interoperability is important to maintain the *business* orientation of the rules repository and allowing for control of BR updates to be retained by the business staff. Outputs include detailed decisions regarding how the automation between the rules repository and the distribution (destination) points will take place and a beta solution. Key actors will include BR vendors, the firm's IT staff, and IT management. Although new techniques are routinely in development, three basic solutions include a business rules engine, a centralized service in an SOA, or a dedicated interface to the application (*going direct*). The solution choice depends on numerous variables including transaction volumes, rule volumes, frequency of rule changes (rule volatility), timeliness, rule scope, and the extent of BR implementations. For example, an application that runs high transaction volumes with near *real-time* processing expectations, would likely require a stand alone dedicated interface (*going direct*) between the rule repository and the application to better insure performance needs are met. Alternatively, a firm that is well established towards SOA (and has completed BR initiatives in other domains) would likely choose to establish their deployments as part of central SOA services. The effects of this step is increased flexibility to design a solution that best fits with business needs and the envisioned IT architecture.

4.6 Test

Insures that the interoperability between the repository and the implementation environment is working appropriately. Inputs in this step include the BRs from the repository via the selected implementation environment and the outputs include test results. Actors include the IT staff, business BR staff, BR vendors and domain experts. Testing procedures will generally focus in three areas; (1) unit testing, (2) integration testing that includes interoperability and connectivity testing from the rule repository to the application program and (3) acceptance testing. This testing should be distinguished from rule logic testing such as rule ambiguity, accuracy, completeness, and redundancy tests that are conducted during rule authoring in the repository stage. The effects of this step is to better insure the interoperability is working (prior to deployment) and learning if the selected environment solution is meeting the organization's business needs.

4.7 Apply

The step of making the final tested BRs fully operational and formally implemented and placed into active operations (e.g. "go live"). Inputs in this step include results and feedback from testing and outputs

include the fully applied BRs. Actors include the IT staff, business staff, and management. Traditional options for deploying new systems are useful here including a direct conversion, parallel start-up, phased roll-out or conducting pilots. When possible, the phased-in approach that spreads the deployment over a logical time sequence, or across segments of the population, or segments of the business offers advantages. Respondents emphasized the importance of preparing short-term fallback policies in case of problems or logical errors. The effects of this step provides a well managed and predictable deployment plan for new BRs, as well as improving the ability of business staff to more swiftly respond and implement BR updates; thus improving the firm's flexibility and ability to rapidly react to changes in competition, legislation and other industry dynamics.

4.8 Maintain

Maintaining the *alignment* environment includes routinely evaluating, realigning, reprioritizing and selecting business domains of where the next BR automation needs to occur, in consideration of larger contextual influences (changing business drivers, new markets, new geographies, ensuing legislative changes, emerging competitive dynamics). Maintaining the *rule management* environment will focus on tactical issues including systematically capturing new or changes in rules, reexamining the organization and patterns to which business units, systems, and processes need rule access and how the access will be established. Rule repository owners should concentrate on effective rule authorship (maximizing rule reuse and accuracy), rule management (balancing rule volatility and churn workloads) and the integrity of the central rule repository (minimizing rule conflicts and concurrency issues). Maintaining the *implementation environment(s)* focuses on insuring consistency with the organization's IT direction, awareness of new interoperability solutions between the repository and distributions sites, enabling rapid deployments, and managing system performance while enabling business users to be rightful owners of BR updates.

5.0 Discussion

Our discussion will briefly compare the BRMLC with the Knowledge Management Lifecycle Model (KMLC) literature and highlight key distinctions between the two. We also revisit the three BR project failures identified in the paper's introduction and illustrate how the BRMLC based can be applied. The BRMLC can be compared to Nissen, Kamel and Sengupta's [39] Knowledge Management Lifecycle

Model (KMLC) which includes the following six phases (*create, organize, formalize, distribute, apply, and evolve*). The authors' refer to this model as an amalgamated model, since it is synthesized from four prior knowledge management lifecycle studies. Whereas the knowledge management model begins with *create*, which the authors' define to include functions of discovery and development of new knowledge [38, page 255], the first two BRMLC phases include *plan* and *capture*. A plan phase is included due to the importance of enterprise wide planning for BR management initiatives and aligning these deployments with related contextual initiatives. The BRMLC *capture* phase is narrower in scope than *create*, with the BRMLC's emphasis towards rule discovery. The KMLC's phases of *organize* (the data that has been captured), *distribute* (the explicit knowledge to stakeholders), and *apply* ('go live' with the knowledge) are similar in nature and intent with those in the BRMLC. The KMLC's *formalize* phase is similar to BRMLC's *authoring* stage, in that they both involve the conversion of existing knowledge from tacit to explicit form. The *authoring* stage is broader in scope, however, by going beyond an initial conversion to an ongoing management of this conversion on a regular and timely basis. Similarly, BRMLC's *maintain* phase is broader in scope than *evolve*, with emphasis towards maintaining and re-aligning the three larger environments of *align, rule management and implementation*.

If we revisit the three BR project failures noted in the paper's introduction, we can further illustrate how a higher contextual level BRMLC perspective can be of benefit. The IRS case, for example, represents a common misconception in BR automation projects that a business rules engine is required in *all* BR automation deployments. Although BRE vendors would likely prefer this 'tunnel vision' myth to continue, as noted in the BRMLC there are several alternative implementation solutions to choose from (SOA, business rules engine, going direct, and others) with advantages and disadvantages for each. The type of failure in the Canadian project is also common in BR implementations. As emphasized by respondents, early phases in the BRMLC expose *related but out-of-scope* opportunities, such as cost reductions with business process reengineering and program efficiencies in legacy code. The temptation is so appealing, that businesses will often postpone the BR implementation to capture the short-term gains. As the delays continue, the BR development ultimately becomes derailed. In the Australian case, project leaders from the vendor and the government clearly lacked a shared understanding regarding the project's scope and in what direction the BR implementation

should be guided. It is precisely in these types of situations that an understanding of the BRMLC at the project's outset and during initial project planning and contractual negotiations would add value. Indeed, all three illustrations highlight the managerial contributions that studies such as this can deliver and that MIS academic researchers are uniquely positioned to provide through presenting a balanced, unbiased perspective grounded in appropriate research methods and transcends specific industries and domains.

6.0 Conclusion

The challenges confronting organizations with managing BRs are growing in complexity as the need for real-time, distributed and consistent decision making across systems, geographies, and channels rise. With the use of structuration research methods, the study collected data and conducted interviews with leading end-users, developers, researchers and thought-leaders from the BR industry. The findings suggest that a lifecycle has indeed emerged in business rules management and it is one that is distinct from the traditional knowledge management lifecycles. Based on synthesizing results from the study, the BRMLC was found to include three high level environments (*align, rule management and implementation*), that are decomposed into eight steps (*plan, capture, organize, author, distribute, test, apply, and maintain*). The primary effects of the BRMLC approach include separating the rule management from the implementation environment, the use of an independent rule repository, shifting control of rule authoring and updates from IT to business staff, and alignment of BR deployments with similar enterprise-wide initiatives.

There are limitations in the study that should be highlighted. First, we examined BR management with greater breadth, than depth. Thus, each step identifies the actors, artifacts, procedures and effects, which can be examined in greater detail. Second, the literature search concentrated in MIS related journals and, to a lesser extent, the business press. Although this approach is consistent with the study's intent, future efforts should consider comparing and supplementing the results to similar streams from computer science and engineering related outlets. Finally, greater longitudinal analysis has traditionally been recommended in applying structuration research methods [43]. The authors did seek to make use of longitudinal considerations by separating the two rounds of interviews by one year. Despite these limitations, we found significant benefits are enabled through effective BR management, including greater flexibility, improved control, higher quality and speed of deploying and managing BRs. Other BRMLC

benefits include exposing buried BRs, preventing BRs from "walking out the door", as well as formally documenting, maintaining and systematically evaluating where rules need to be deployed. Recommendations for future research include a BRMS technology diffusion, as managers continue to push automated BR management across their organizations. Also, the dynamics that occur between IT and the business staff during BR deployments should be more closely examined and has much to offer to the IT – business alignment literature. Furthermore, the literature search results revealed that certain areas of the BRMLC (such as the rule repository, authoring and organize) have had very few studies, if any, in MIS literature despite their growing importance and influences.

	Align	Rule Management	Implementation
Owners	Senior Business & IT Leaders	Business Operational Staff	IT Staff
Organization Contexts	Enterprise-wide Vision IT Directional Setting	SBVR, VSC, rule volatility Web semantics, rule volumes Business process, enforcement	SOA, Channel Mgmt Domain scope, BPM, WFM
Time Horizon	Long-term Based on organization's longer-term vision.	Short-term Real time with active execution, based on rule duration.	Mid-term Based on IT infrastructure changes and direction.
Rate of Change	Low	High	Low to Moderate
Sources	Corporate Strategic Vision Senior Management	Legislative, regulatory, competitive industry norms and many others	Rule repository

Figure 2. Business Rules Management Lifecycle Environments

Table 1– Structured Interview Questions and Topics

- What process steps are conducted for business rules management?
- How does business rule management align / fit with other initiatives in the firm or industry? Are there noteworthy contradictions?
- What are the effects (and consequences) of automated business rules management? What features of the context influence structuration?
- What is the relationship between IT and the business units regarding business rules management?
- What are the consequences of business rules management on this relationship?
- Is the business rules management process short-term or permanent? What evidence exists to suggest the longer-term need for a formal business rules management process?
- Who are the key actors in the business rule management process? Who are the critical stakeholders?
- What is your (the interviewees) role in the business rule management process?
- How many business rule deployments / implementations have you participated?
