ABSTRACT

The usefulness of the many on-line journals and scientific digital libraries that exist today is limited by the lack of a service that can federate them through a unified interface. The Open Archive Initiative (OAI) is one major effort to address technical interoperability among distributed archives. The objective of OAI is to develop a framework to facilitate the discovery of content in distributed archives. In this paper, we describe our experience and lessons learned in building Arc, the first federated searching service based on the OAI protocol. Arc harvests metadata from several OAI compliant archives, normalizes them, and stores them in a search service based on a relational database (MySQL or Oracle). At present we have over 165K metadata records from 16 data providers from various domains.

1. INTRODUCTION

A number of free on-line journals and scientific digital libraries exist today, however, there is a lack of a federated service that provides a unified interface to all these libraries. The Open Archive Initiative (OAI) [1] is one major effort to address technical interoperability among distributed archives. The objective of OAI is to develop a framework to facilitate the discovery of content in distributed archives. The OAI framework supports data providers (archives) and service providers. The service provider develops value-added services that are based on the information collected from data providers. These value-added services could take the form of cross-archive search engines, linking systems, and peer-review systems. OAI is becoming widely accepted and there are many archives currently or soon-to-be OAI compliant. Arc (http://arc.cs.odu.edu) is the first federated search service based on the OAI protocol, and its concept originates from the Universal Preprint Service (UPS) prototype [2]. We encountered a number of problems in developing Arc. Different archives have different format/naming conventions for specific metadata fields that necessitate data normalization. Arbitrary harvesting can over-load the data provider making it unusable for normal purposes. Initial harvesting when a data provider joins a service provider requires a different technical approach than periodical harvesting that keeps the data current.

2. Architecture

The Arc architecture is based on the Java servlets-based search service that was developed for the Joint Training, Analysis and Simulation Center (JTASC) [3]. This architecture is platform independent and it can work with any web server. Moreover, the changes required to work with different databases are minimal. Our current implementation supports two relational databases, one in the commercial domain (Oracle), and the other in public domain (MySQL). The architecture improves performance over the original UPS architecture by employing a three-level caching scheme [3]. Figure 1 outlines the major components; however, for brevity we discuss only the components relevant to this paper.

2.1 Harvester

Data providers are different in data volume, partition definition, service implementation quality and network connection quality. All these factors influence the harvesting procedure. Historical and newly-published data harvesting have different requirements. When a data provider joins a service provider for the first time, all past data (historical data) needs to be harvested, followed by periodic harvesting to keep the data current. Historical data are high-volume and more stable, the harvesting process generally runs once, and a chunk-based harvest is preferred to reduce accessing time and data...
provider overhead. To harvest newly published data, data size is not the major problem but the scheduler must be able to harvest new data as soon as possible and guarantee completeness – even if data providers provide incomplete data for the current date. The OAI protocol provides flexibility in choosing the harvesting strategy; theoretically, one data provider can be harvested in one simple transaction, or one is harvested as many times as the number of records in its collection. But in reality only a subset of this range is possible; choosing an appropriate harvesting method has not yet been made into a formal process. We defined four harvesting types in Arc: (a) bulk-harvest of historical data (b) bulk-harvest of new data (c) one-by-one-harvest of historical data (d) one-by-one-harvest of new data. From our tests, these four strategies in combination can fulfill various requirements of a particular collection.

2.2 Database Schema

OAI uses Dublin Core (DC) as the default metadata set. All DC attributes are saved in the database as separate fields. The archive name and partition are also treated as separate fields in the database for supporting search and browse functionality. In order to improve system efficiency, most fields are indexed using full-text properties of the database, which makes high performance queries over large dataset possible. The search engine communicates with the database using JDBC and Connection Pool.

2.3 Search Interface specification

The search interface supports both simple and advanced search as well as result sorting by date stamp, relevance ranking and archive. Simple search allows users to search free text across archives. Advanced search allows user to search in specific metadata fields. Users can also search/browse specific archives and/or archive partitions in case they are familiar with specific data provider. Author, title, abstract search are based on user input, the input can use boolean operators (AND, OR, NOT). Archive, set, type, language and subject use controlled vocabularies and are accumulatem from the participating archives’ source data.

3. Results

We maintain two test sites, the public Arc cross archive service and another site for the OAI alpha test only. So far, in the public service, we have seven archives available for search (Table 1). In the OAI alpha test site, we have nine archives across different domains, including documents from Heinonline.org, Open Video Project, Language Resource Association, Library of Congress and other organizations. The alpha test data is not open to the public.

4. Lessons learned

Little is known about the long-term implications of a harvest-based digital library, but we have had the following initial experiences. The effort of maintaining a quality federation service is highly dependant on the quality of the data providers. Some are meticulous in maintaining exacting metadata records that need no corrective actions. Other data providers have problems maintaining even a minimum set of metadata and the records harvested are useless. We have not yet fully addressed the issue of metadata normalization. Some normalization was necessary to achieve a minimum presentation of query results. However, we did so on an ad hoc basis with no formal definition of the relationship mappings. A controlled vocabulary will be of great help for a cross archive search service to define such metadata fields as ‘subject’ or even ‘organization’. XML syntax errors and character-encoding problems were surprisingly common and could invalidate entire large data sets. We also faced a trade-off in frequency of harvests: too many harvests could over burden both the service and data providers, and too few harvests allow the data in the service provider to potentially become stale.
